AMENDMENTS TO THE CLAIMS

This listing of claims will replace all prior versions, and listings, of claims in the application.

Listing of Claims:

- 1. (Cancelled)
- 2. (Currently Amended) The semiconductor integrated-circuit device, according to claim 4 comprising:

a plurality of flip-flop circuits for acquiring and holding signals by use of clock signals; and

a plurality of signal transferring paths each including a plurality of CMOSconstructed logic gate circuits provided between one pair of flip-flop circuits within said plurality of flip-flop circuits;

said plurality of signal transferring paths further including;

a first signal transferring path in which said plurality of logic gate circuits are constituted by enhancement-type MOSFETs, said first signal transferring path providing a signal transferring delay time equal to, or less than, a permissible signal transferring delay time;

a second signal transferring path in which, among all said plurality of logic gate circuits, a logic gate circuit having a delay time longer than said permissible signal transferring delay time when the logic gate circuit is constituted by an enhancement-type MOSFET is replaced with a depletion-type MOSFET so that the

Art Unit: 2819

Docket No.: 520.43528X00

Page 4

second signal transferring path may provide a signal transferring delay time equal to, or less than, said permissible signal transferring delay time; and,

wherein the depletion-type MOSFET constituting the logic gate circuit to be replaced is formed by applying a manufacturing step for depletion to a MOSFET having the same pattern and size as those of the enhancement-type MOSFET that has not been replaced.

3. (Currently Amended) The semiconductor integrated-circuit device, according to claim 1, comprising: comprising:

a plurality of flip-flop circuits for acquiring and holding signals by use of clock signals; and

a plurality of signal transferring paths each including a plurality of CMOSconstructed logic gate circuits provided between one pair of filp-flop circuits within said plurality of flip-flop circuits:

said plurality of signal transferring paths further including:

a first signal transferring path in which said plurality of logic gate circuits are constituted by enhancement-type MOSFETs, said first signal transferring path providing a signal transferring delay time equal to, or less than, a permissible signal transferring delay time;

a second signal transferring path in which, among all said plurality of logic gate circuits, a logic gate circuit having a delay time longer than said permissible signal transferring delay time when the logic gate circuit is constituted by an enhancement-type MOSFET is replaced with a depletion-type MOSFET so that the

Art Unit: 2819

Docket No.: 520.43528X00

Page 5

second signal transferring path may provide a signal transferring delay time equal to, or less than, said permissible signal transferring delay time; and

enhancement-type MOSFETs with high threshold voltage, enhancement-type MOSFETs with low threshold voltage, and depletion-type MOSFETs;

wherein said flip-flop circuits and said first signal transferring path are constituted by said enhancement-type MOSFETs with high threshold voltage; and

wherein said second signal transferring path is constituted by said enhancement-type MOSFETs with high threshold voltage and said enhancement-type MOSFETs with low threshold voltage, by said enhancement-type MOSFETs with low threshold voltage, by said enhancement-type MOSFETs with low threshold voltage and said depletion-type MOSFETs, or by said depletion-type MOSFETs.

- 4. (Original) The semiconductor Integrated-circuit device according to claim 3, further comprising MOSFETs with high withstand voltage and high threshold voltage, wherein input/output circuits for exchanging signals with external terminals are constituted by said MOSFETs with high withstand voltage and high threshold voltage, and said MOSFETs with high threshold voltage.
- 5. (Original) The semiconductor integrated-circuit device according to claim 3, further comprising a memory circuit, wherein a memory array in said memory circuit is constituted by said enhancement-type MOSFETs with high threshold voltage, and a peripheral circuit of this memory array is constituted by said enhancement-type MOSFETs with low threshold voltage.

Art Unit. 2819

Docket No.: 520.43528X00

Page 6

6. (Original) The semiconductor integrated-circuit device according to claim 3, further comprising analog circuits, wherein, among all said analog circuits, a MOSFET circuit constituting a current source is formed using said enhancement-type MOSFETs with high threshold voltage, and a differential MOSFET circuit and a cascade-connected circuit are formed using said enhancement-type MOSFETs with high threshold voltage.

- 7. (Currently Amended) The semiconductor integrated-circuit device according to claim 12, wherein, in a standby state in which no signal processing is performed through a signal transferring path, said deletion-type MOSFETs have substrate bias voltage applied in a direction of decreasing a source-to-drain current decreases.
 - 8. (Cancelled)
- 9. (Currently Amended) The CMOS circuit operational speeding-up method, according-to-claim 8, comprising:

a first step of designing a signal-processing circuit using enhancement type

MOSFETs, sald signal-processing circuit comprising a plurality of flip-flop circuits for
acquiring and holding signals by use of clock signals, and a plurality of CMOSconstructed logic gate circuits provided between one pair of flip-flop circuits within
said plurality of flip-flop circuits;

Application No.: 10/781,746 Art Unit: 2819

Docket No.: 520.43528X00

Page 7

a second step of extracting, from said plurality of signal transferring paths, a signal transferring path whose signal transferring delay time that exceeds a permissible signal transferring delay time;

a third step of replacing, among said plurality of logic gate circuits constituting said signal transferring path that has extracted, a logic gate circuit having a delay time longer than said permissible signal transferring delay time when the logic gate circuit is constituted by an enhancement-type MOSFET with a depletion-type MOSFET so that said signal transferring path may provide a signal transferring delay time equal to or less than said permissible signal transferring delay time; and

wherein said third step is followed by said second step after, of all said enhancement-type MOSFETs constituting said signal transferring paths, a MOSFET having a maximum delay time has been replaced with the depletion-type MOSFET.

- 10. (Original) The CMOS circuit operational speeding-up method according to claim 9, wherein, if said signal transferring path to be extracted is absent, all the delay times of said plurality of signal transferring paths are judged to be equal to or less than said permissible signal transferring delay time.
- 11. (Original) The CMOS circuit operational speeding-up method according to claim 10, wherein, when, in said third step, all MOSFETs of said signal transferring paths are said depletion-type MOSFETs and the signal transferring delay time thereof is taken as a first time, processing returns to said first step and said permissible signal transferring delay time is set as said first time.

Art Unit: 2819

Docket No.: 520.43528X00

Page 8

12. (Currently Amended) The CMOS circuit operational speeding-up method according to claim 89, in which, in said third step, among said plurality of logic gate circuits constituting said signal transferring path that has extracted, a logic gate circuit having a delay time longer than said permissible signal transferring delay time when the logic gate circuit is constituted by an enhancement-type MOSFET is replaced with second enhancement-type MOSFETs smaller than said enhancement-type MOSFETs in terms of threshold voltage so that said signal transferring path extracted may provide a signal transferring delay time equal to, or less than, said permissible signal transferring delay time.

13. (Currently Amended) The CMOS circuit operational speeding-up method according to claim 89, wherein the signal-processing circuit in said first step is one mounted on an existing semiconductor integrated-circuit device.

14. (Cancelled)

15. (Currently Amended) A semiconductor integrated-circuit device, wherein: a signal input block of a first combination circuit and that of a second combination circuit are connected across an output of a first flip-flop;

a signal input block of a third combination circuit is connected to the signal input blocks of said first and second combination circuits;

an input of a second flip-flop is connected to the signal output block of said third combination circuit;

Art Unit: 2819

Docket No.: 520.43528X00

Page 9

said first, second, and third combination circuits are constituted by one or more logic gates; and

part of said logic gates is constituted by a depletion-type MOSFET, wherein the logic gates in said semiconductor integrated circuits are further formed with first MOSFETs of the enhancement type whose threshold voltage is a first threshold voltage, and second MOSFETs of the enhancement type whose threshold voltage is a second threshold voltage, said first threshold voltage being higher than said second threshold voltage.

16. (Currently Amended) The semiconductor integrated-circuit device. according to claim-14, comprising:

one or more logic gates between an output of a first flip-flop and an input of a second flip-flop;

wherein part of said plurality of logic gates is constituted by a depletion-type MOSFET; and

wherein the logic gates in said semiconductor integrated circuits are further formed with first MOSFETs of the enhancement type whose threshold voltage is a first threshold voltage, and second MOSFETs of the enhancement type whose threshold voltage is a second threshold voltage, said first threshold voltage being higher than said second threshold voltage.

17. (Original) The semiconductor integrated-circuit device according to claim 16, further comprising input/output circuits for exchanging signals with external terminals, wherein said input/output circuits are constituted by a plurality of

Art Unit: 2819

Docket No.: 520.43528X00

Page 10

MOSFETs having said first threshold voltage, and said plurality of MOSFETs are MOSFETs different in withstand voltage.

18. (Original) The semiconductor Integrated-circuit device according to claim 16, further comprising a memory circuit, wherein a memory array of said memory circuit is constituted by enhancement-type MOSFETs of said first threshold voltage, and a peripheral circuit of said memory circuit are constituted by an enhancementtype MOSFET of said second threshold voltage.

19. (Original) The semiconductor Integrated-circuit device according to claim 16, further comprising analog circuits, wherein among said analog circuits, a MOSFET circuit constituting a current source is formed using enhancement-type MOSFETs of sald first threshold voltage, and a differential MOSFET circuit and a cascade-connected circuit are formed using said enhancement-type MOSFETs of said second threshold voltage.

20. (Currently Amended) The semiconductor integrated-circuit device according to claim 4416, wherein, in a standby state in which no signal processing is performed through a signal transferring path, said deletion-type MOSFETs have substrate bias voltage applied in a direction of decreasing a source-to-drain current decreases.
